A region where no oscillatory layer can exist

$$m_0 > m_*(\alpha,\beta), \quad m_1 \geq m_*(\alpha,\beta), \qquad m_* = [-(\alpha+1) + \sqrt{(\alpha+1)^2 - 4\beta}\,]/(2\alpha)$$

Convergence region lies toward larger m_0 and m_1 from these faces.

Convergence region lies toward larger m_0 and m_1 from these faces.

Analytical storage proof, γ = 0. Assumptions: α > 0, β > 0, positive discriminant and r > 1.
The m_0 face contains neutral periodic orbits. The m_1 face is a sufficient-sector edge, not an exact global boundary.
The figures show a bounded part of an unbounded slope sector; no absence claim is made outside it.
