Finite-iterate homoclinic-tangency estimates
A | The returning branch develops a quadratic fold
B | The long cycle spends extra returns near that saddle
Final normal distance (units of 1e-7)
Displacement on initial unstable line (millionths)
Beta offset -1e-07
Beta offset +0e+00
Beta offset +1e-07
Tangent stable line
Distance to the short saddle on the section
Successive inverted half-section returns
75 peaks
85 peaks
Finite-iterate tangency estimates cluster near beta = 14.30635909996.
Six approximations span 1.12e-12; this spread is not an error bound or a proof of an exact manifold tangency.
