A homoclinic tangency in a region of hidden periodic attractors

72 transverse affine flights | Interval checks at 140 and 160 digits | Equilibrium exclusion uniform in β

A Numerical connection near β*

B Four strict signs for exact manifolds

Parameter faces: scale 10^{-11}

Derivative faces: scale 30

C The logical implication

Verified local dynamics

Quadratic tangency; nonzero unfolding; dissipative saddle; complete flight paths.

↓

Classical parameter theorem

Some nearby β values support infinitely many simultaneous periodic sinks.

↓

Verified equilibrium exclusion

Every one of these attracting cycles has a hidden basin.

The numerical curve illustrates the connection. Infinity follows from the certified hypotheses and the cited theorem; no decimal β_∞ or infinite orbit list is computed.
