Why this sequence has thinner and more sensitive layers

Extra returns near one saddle predict both parameter precision and temporary amplification.

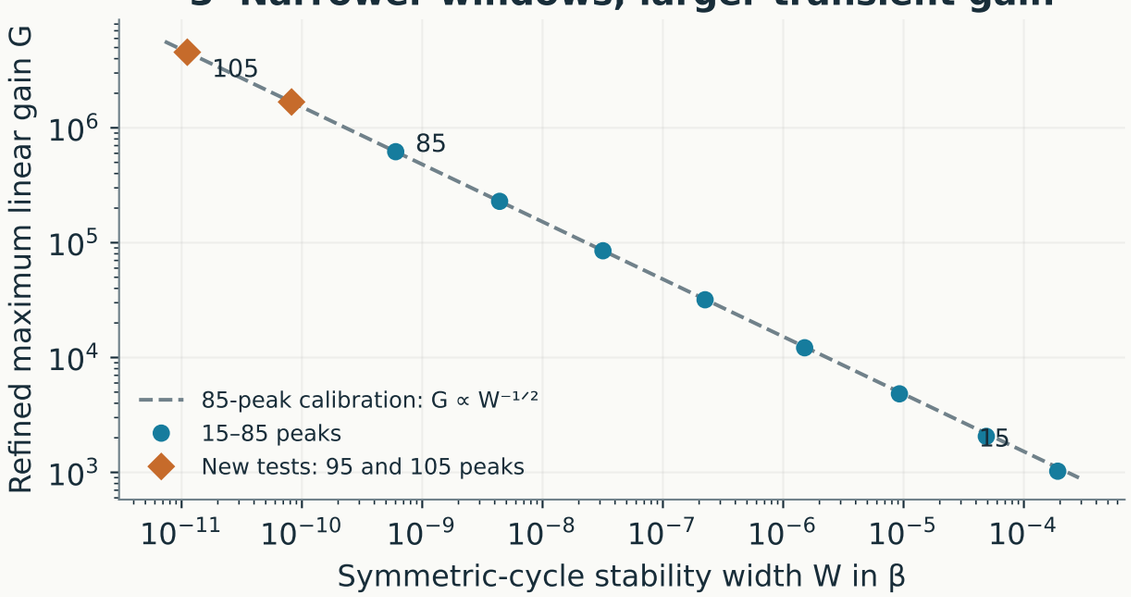

1 More returns near the same saddle

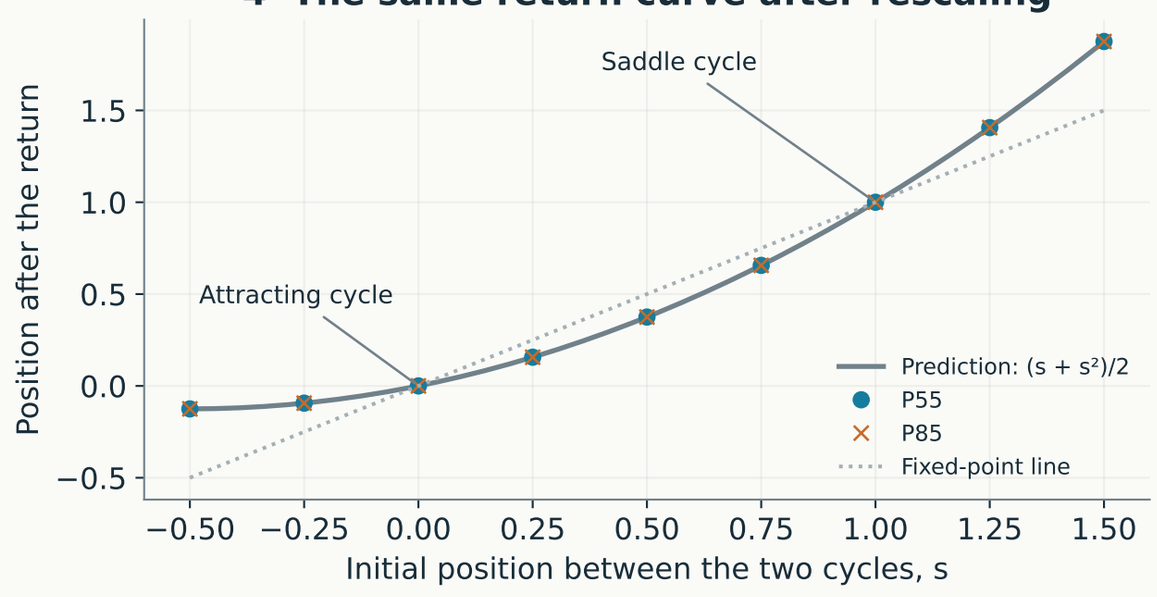

2 Large growth during an attracting cycle

3 Narrower windows, larger transient gain

4 The same return curve after rescaling

Numerical evidence for one period-adding sequence at α = 9, $m_0 = -8/7$, $m_1 = -5/7$.
Linear gain is measured transverse to the flow; it is not a finite basin-escape threshold.
